WATERBURY ARSENAL LABORATORY

REPORT NO. REPT NO. WAL 110/706

First and Final Report on Problem R-3, U

22 September 1941.

Resistance of Various Materials Components of Flight Curtains  
to Perforation by Flak-Simulating Projectiles

1. As a result of a request from the Office, Chief of Ordnance<sup>1</sup>, a program of investigation of various materials proposed as components of flak-resistant curtains has been conducted at this arsenal over the past several months.

2. As originally contemplated, this program would have included the development of a projectile which would simulate reproducibly and measurably the impact of fragments of high-explosive anti-aircraft shell. Indeed, a projectile similar in design to the cal. .20 aircraft-simulating projectile, G-2<sup>2</sup>, has been tested. However the lack of correlation between the results of actual fragmentation tests of 20mm. high-explosive projectiles and the results of tests with the cal. .20 projectile or any other single projectile caused an abandonment of the contention that any one projectile may be developed which may reproducibly and measurably simulate the effect of service impact of high-explosive shell fragments against all materials.

3. Nevertheless several materials have been tested at this arsenal with various projectiles and the results of these tests may be of some use in the formation of an opinion as to the relative resistance characteristics of these materials to the attack of fragments of high-explosive anti-aircraft shell. It is the purpose of this report to present these results.

1. O.O. 170.1/3478 - Item 70.1/7315 - 18 May 1941.

4. Hadfield manganese steel of the standard composition and a Hadfield manganese steel containing 3% nickel were tested as were several ferritic steels and aluminum alloys. The results of these tests as well as other data pertaining to the tested materials are included in Table I.

5. In earlier tests in which similar projectiles were fired against materials of a lighter gauge (.040" to .050") Hadfield manganese steel has consistently exhibited resistance characteristics superior to those of other materials. In the present tests this superiority is maintained in the lighter gauges (around .060") but is relinquished when the gauges become greater. The relative resistance of these materials to attack with fragments of larger high-explosive shell may, however, not follow this trend. The inversion of relative superiority of the austenitic and ferritic steels as the gauge increases is believed attributable to the fact that the e/d relationship is changing rapidly since the projectile diameter is constant. It is believed that were the e/d ratio to remain constant, the relative resistance of the materials involved would not vary.

6. The lack of correlation between the results of tests of materials under actual fragmentation of 20mm. high-explosive shell and the results of tests with fragment-simulators has been referred to above. Technical difficulties militate against a practical evaluative test of materials under actual fragmentation of high-explosive shell of larger caliber. There can, therefore, not be determined accurately whether any correlation exists between the results of the subject tests and service conditions.

7. It is therefore suggested that the results of actual fragmentation tests with 20mm. high-explosive shell be used as a basis for the evaluation of materials proposed as components of flak-resistant curtains as well as for the evaluation of materials proposed as components of body armor assemblies. It is contended that the fragmentation pattern of larger caliber shell may not vary greatly from that of the evaluable 20mm. shell and that the relative resistance of materials at any given ratio of e/d should not vary greatly provided the manner of presentation of the projectile remains fairly constant.
